

Spain's coronavirus rate triples in three weeks after lockdown easing

Madrid, July 21 (RHC)-- The prevalence of coronavirus in Spain has risen three-fold over the last three weeks as authorities struggle to contain a rash of fresh clusters, mainly in the Catalonia and Aragon regions, Health Ministry data showed on Monday.

After registering thousands of cases and hundreds of deaths per day during an early April peak, Spain succeeded in slowing the number of new infections to a trickle.

But since restrictions on movement were lifted and Spaniards relaxed back into daily life, some 201 new clusters have appeared, with heavy concentrations in and around the Catalan cities of Barcelona and Lleida.

Over the weekend 4,581 new cases were recorded, bringing the total to 264,836. More than 28,000 people have died.

The occurrence of the novel coronavirus has jumped from eight cases per 100,000 inhabitants at the end of June, when the country's state of emergency ended, to 27 per 100,000, deputy health emergency chief

Maria Sierra told a news conference on Monday.

"Where measures have been relaxed is where these clusters appear," Health Minister Salvador Illa said. "We're talking about gatherings of extended family and spaces associated with nightlife."
